UGT1A1 Gene Analysis

Variants in the UGT1A1 gene cause decreased production of the functional enzyme, UDP-glucuronosyltransferase, responsible for bilirubin metabolism leading to hyperbilirubinemia. The severity of the functional deficiency of hepatic UGT1A1 is determined by the genetic variant(s); thus, the resulting phenotypic spectrum is variable. Crigler-Najjar syndrome is a rare, autosomal recessive disorder resulting from severe functional deficiency of hepatic UGT1A1 and characterized by intermediate-severe hyperbilirubinemia, jaundice, and risk for kernicterus. Gilbert syndrome is a common inherited condition resulting from a mild decrease in UGT1A1 activity, and individuals may be asymptomatic or have mild, fluctuating hyperbilirubinemia and intermittent jaundice.

The UGT1A1 enzyme is also involved in the metabolism of certain drugs, including irinotecan, a topoisomerase I inhibitor, and atazanavir, an antiretroviral protease inhibitor. UGT1A1 variants resulting in enzyme deficiency are associated with an increased risk for drug toxicity.

DISEASE OVERVIEW

Incidence
- Gilbert syndrome: 3-7% of U.S. population
- Crigler-Najjar syndrome: 1/million

Symptoms
- Inherited unconjugated hyperbilirubinemia without hemolytic anemia or liver dysfunction
- Spectrum of clinical phenotypes differentiated by level of residual hepatic uridine diphosphate glucuronosyltransferase (UGT) 1A1 enzyme activity, serum bilirubin levels, and response to phenobarbital loading
- Crigler-Najjar syndrome type I (MIM #218800)
  - Most severe phenotype resulting from absence/near absence of hepatic UGT1A1 activity
  - Severe hyperbilirubinemia, jaundice, and risk for kernicterus
  - Refractory to phenobarbital
- Crigler-Najjar syndrome type II (MIM #606785)
  - Greaterly reduced hepatic UGT1A1 activity (typically <10% of normal)
  - Intermediate hyperbilirubinemia, jaundice, and low risk for kernicterus
  - Responsive to phenobarbital loading
- Gilbert syndrome (MIM #143500)
  - Decreased UGT1A1 activity
  - Mild, fluctuating hyperbilirubinemia
  - Commonly asymptomatic, jaundice may be intermittent
  - Not associated with kernicterus

Pathophysiology
- UGT1A1 enzyme metabolizes endogenous substances (eg, bilirubin) and drugs (eg, irinotecan)
- Irinotecan (CPT-11, Camptosar, Onivyde) is a topoisomerase I inhibitor
  - Interrupts DNA replication in cancer cells, causing cell death
  - Prodrug irinotecan is metabolized to active metabolite SN-38, and inactivated by UGT1A1
  - Decreased UGT1A1 activity reduces ability to metabolize SN-38 to inactive form
- Atazanavir (Reyataz), an antiretroviral protease inhibitor, inhibits hepatic UGT1A1

Pharmacogenetic Indications
- Irinotecan
  - Approved for treatment of metastatic colorectal cancer
  - May be used in metastatic lung, brain, and breast cancer
  - Irinotecan is associated with severe diarrhea and neutropenia in 20-35% of individuals
  - Toxicity of irinotecan is associated with specific UGT1A1 genotype variants in patients receiving high-dose
- Atazanavir
  - Approved human immunodeficiency virus (HIV) type 1 protease inhibitor
  - Risk for premature bilirubin-related discontinuation associated with UGT1A1 genotype
  - CPIC Guideline for Atazanavir and UGT1A1 is available.
GENETICS

Gene
UGT1A1

Inheritance
Autosomal recessive for Gilbert and Crigler-Najjar syndromes; de novo variants are rare

Variants
- Functional deficiency of UGT1A1 varies depending on specific genetic variant(s)
- UGT1A1 pathogenic variants in coding region
  - Homozygosity or compound heterozygosity commonly results in Crigler-Najjar syndrome
  - Homozygosity for the mildly pathogenic variant UGT1A1*6 (rs4148323, c.211G>A, p.Gly71Arg) is a common cause of Gilbert syndrome in East Asians
- Polymorphic TA repeats in the UGT1A1 promoter region, (TA)nTAA, rs3064744, NC_000002.11:g.234668881_234668882TA[n], (HGVS, n=5, 6, 7, or 8)
  - 6 is the most common number of repeats, also known as UGT1A1*1 (TA)6
  - Homozygosity for 7 repeats, *28 (TA)7, is a common cause of Gilbert in Caucasians/African Americans, with reduced expression of UGT1A1 to ~60-80% of the wild type

TEST INTERPRETATION

Sensitivity/Specificity
- Analytical sensitivity and specificity: >99%
- Clinical sensitivity/specificity: estimated risk of irinotecan toxicity by genotype in Caucasian patients with colorectal cancer

Limitations
Gilbert and Crigler-Najjar Syndromes (UGT1A1) Sequencing
- Diagnostic errors can occur due to rare sequence variations
- UGT1A1 regulatory region variants other than the (TA)nTAA promoter polymorphisms, *1 TA(6), *36 TA(5), *28 TA(7), and *37 TA(8), will not be analyzed
- Deep intronic variants, large deletions/duplications/insertions, and gene conversion events will not be detected
- Variants of uncertain clinical significance within the UGT1A1 coding region will not be reported for pharmacogenetic indications
- Genetic and nongenetic factors other than UGT1A1, may contribute to irinotecan toxicity and efficacy, and risk for bilirubin-related discontinuation of atazanavir

UDP Glucuronosyltransferase 1A1 (UGT1A1) Genotyping
- Variants other than the (TA)nTAA promoter polymorphisms, *1 TA(6), *36 TA(5), *28 TA(7), and *37 TA(8), will not be detected
- Genetic and nongenetic factors other than UGT1A1 may contribute to irinotecan toxicity and efficacy, and risk for bilirubin-related discontinuation of atazanavir
- Diagnostic errors can occur due to rare sequence variations
