Pemphigus Antibody Panel - Epithelial Cell Surface Antibodies and Desmoglein 1 and Desmoglein 3 Antibodies, IgG

Pemphigus Antibody Panel, IgG

See Note

IMMUNODERMATOLOGY REPORT

Specimen(s):
1. Serum specimen

Clinical/Diagnostic Information:
No clinical information provided.

DIAGNOSTIC INTERPRETATION

Negative/normal IgG Pemphigus Antibody Panel
(See Results and Comments)

RESULTS

Indirect Immunofluorescence
---------------------------------------

Cell Surface IgG Antibodies

IgG: Negative, monkey esophagus substrate
Negative, intact human skin substrate

Reference Range:
Positive - Titer greater than 1:10
Borderline - Titer 1:10
Negative - Titer less than 1:10

(H = high/positive)

Enzyme Linked Immunosorbent Assay (ELISA)

Desmoglein (DSG) 1 and 3 IgG Antibodies

IgG desmoglein 1 antibodies: 1 unit

Reference Range:
Positive (H) = Greater than 20 units
Borderline/indeterminate = 14-20 units
Negative = Less than 14 units

IgG desmoglein 3 antibodies: 1 unit

Reference Range:
Positive (H) = Greater than 20 units
Borderline/indeterminate = 9-20 units
Negative = Less than 9 units

(H = high/increased; units = units/mL serum)

---

H - high L - low * - abnormal C - critical
COMMENTS
Specific
----------------------------------------------------------

These negative/normal results for IgG cell surface antibodies by indirect immunofluorescence and ELISA testing are against, but do not rule out, the diagnosis of active pemphigus vulgaris, pemphigus foliaceus, or other IgG pemphigus variants.

Detection and levels of diagnostic antibodies may fluctuate over time with disease expression. Clinical correlation is needed with consideration for monitoring antibody profiles and levels with persistent or progressive disease activity.

General
----------------------------------------------------------

Greater than 80 percent of patients with pemphigus have positive epithelial cell surface antibodies in their sera identified by indirect immunofluorescence. Serum antibody titers correlate with disease activity. Cell surface antibodies are implicated in the pathophysiology of pemphigus and are not typically detected in normal individuals, in patients with other diseases or in patients with pemphigus whose disease activity is minimal and/or under therapeutic control.

Antibodies in serum from individuals with pemphigus bind to desmogleins, which are calcium-dependent adhesion molecules in cell surface desmosomes; such antibodies are detected by enzyme linked immunosorbent assay (ELISA) testing. Specific reactivity to the type of desmoglein may be helpful in determining pemphigus subtypes; IgG desmoglein 1 autoantibodies predominate in patients with pemphigus foliaceus, and IgG desmoglein 3 autoantibodies, with or without accompanying desmoglein 1 autoantibodies, predominate in patients with pemphigus vulgaris. Overlapping expression with autoantibodies to both desmogleins 1 and 3 typically is associated clinically with both mucosal and skin lesions. ELISA testing for IgG desmoglein 1 and IgG desmoglein 3 antibodies is highly sensitive, with greater than 90 percent of pemphigus patients showing increased levels of one or both antibodies. Desmoglein antibodies are not increased in normal individuals. IgG desmoglein levels by ELISA testing also correlate with disease activity.

TESTING METHODS
Indirect Immunofluorescence
-----------------------------------------

Cell Surface IgG Antibodies
The patients serum is progressively diluted in calcium-containing buffer beginning at 1:10 in three two-fold screening dilutions, layered on sections of intact normal human skin and monkey esophagus substrates, and stained with fluorescein-conjugated anti-IgG using Analyte Specific Reagents (ASRs). When positive, the serum is further diluted in two-fold reductions to the limiting dilution of antibody detection or to a maximum dilution of 1:40,960. These tests were developed and their performance characteristics determined by the Immunodermatology Laboratory at the University of Utah. They have not been cleared or approved by the U.S. Food and Drug Administration. ASRs are used in many laboratory tests necessary for standard medical care and generally do not require FDA approval. These tests should not be regarded as investigational or for research only. [Immunofluorescence studies, one antibody on two substrates]

Enzyme Linked Immunosorbent Assay (ELISA)
-----------------------------------------

Desmoglein 1 and desmoglein 3 IgG serum antibody levels determined by U.S. Food and Drug Administration-approved ELISAs (Mesacup, MBL International). [Two ELISAs]
