EGFR T790M Mutation Detection in Circulating Tumor DNA by Digital Droplet PCR
ARUP test code 2012868

EGFR T790M Result

Detected *

This result has been reviewed and approved by Georgios Deftereos, M.D.

A T790M mutation was detected in the EGFR gene. The mutant allele frequency is 7.21 percent.

BACKGROUND INFORMATION: EGFR T790M Mutation Detection in Circulating Cell-Free DNA by Digital Droplet PCR

Determining EGFR mutation status is useful in identifying patient eligibility for tyrosine kinase inhibitor (TKI) therapy. Clinical resistance to initial generation TKI's and subsequent response to newer generation TKI's have been associated with the T790M mutation.

Methodology: Circulating DNA is extracted and amplified. Mutation status and quantitation for EGFR T790M is determined by digital droplet PCR.

Limitations: Mutations in other locations within the EGFR gene or in other genes will not be detected.

Limit of Detection: Based upon amplifiable DNA, the limit of detection ranges from 0.5% to less than 0.02% mutant alleles.

Clinical Disclaimer: Results of this test must always be interpreted within the clinical context and other relevant data, and should not be used alone for the diagnosis of malignancy.

Test developed and characteristics determined by ARUP Laboratories. See Compliance Statement B: aruplab.com/CS
