**BCR-ABL1 Qualitative and Quantitative Testing**

**Tests to Consider**

**BCR-ABL1, Qualitative with Reflex to BCR-ABL1 Quantitative 2005010**

**Method:** Reverse Transcription Polymerase Chain Reaction

- Recommended when submitting initial diagnostic specimen for CML or Ph+ ALL when the BCR-ABL1 fusion form is not known (no previous BCR-ABL1 testing performed) or is unclear
- If qualitative test is positive for the presence of the p210 (major breakpoint), p190 (minor breakpoint), or p230 (micro breakpoint), the corresponding quantitative test is performed

**BCR-ABL1, Major (p210), Quantitative 2005017**

**Method:** Quantitative Reverse Transcription Polymerase Chain Reaction

- Appropriate for diagnosis and monitoring of individuals with CML or a subset of B-cell ALL
- BCR-ABL1 major (p210) fusion form is present in almost all cases of CML and in a subset of ALL cases (e13a2 or e14a2 transcripts)

**BCR-ABL1, Minor (p190), Quantitative 2005016**

**Method:** Quantitative Reverse Transcription Polymerase Chain Reaction

Useful in cases of Philadelphia chromosome positive (Ph+) ALL to quantify the BCR-ABL1 p190 fusion form

**Related Tests**

**BCR-ABL1 Mutation Analysis for Tyrosine Kinase Inhibitor Resistance by Next Generation Sequencing 2008420**

**Method:** Massively Parallel Sequencing

- Useful for patients with an established diagnosis of a BCR-ABL1 positive (Ph+) leukemia to determine if a mutation is present that would interfere with response to TKI therapy in Ph+ ALL or CML
- Detects all common mutations, including T315I

---

**Typical Testing Strategy**

**Chronic Myelogenous Leukemia**

- Bone marrow cytogenetic studies and quantitative reverse transcription polymerase chain reaction (RT-PCR) measurement of BCR-ABL1 transcript levels recommended before treatment initiation
- Quantitative RT-PCR is used to monitor response to TKI therapy
- BCR-ABL1 kinase domain mutation analysis (massively parallel sequencing) is useful to monitor TKI therapy and disease progression

**Acute Lymphoblastic Leukemia**

- Evaluation for the presence of recurrent genetic abnormalities at diagnosis using karyotyping and/or fluorescence in situ hybridization (FISH) assays
- MRD assessment on bone marrow using flow cytometry and quantitative RT-PCR at the completion of therapy and at regular intervals to monitor progress

**Disease Overview**

**Chronic Myelogenous Leukemia**

**Incidence**

- 1/555 in the U.S.\(^1\)
  - Represents 15% of all adult leukemias\(^2\)
- Median age of onset is 67 years

**Acute Lymphoblastic Leukemia**

**Incidence**

1.58/100,000 in US\(^3\)

- 75-80% of acute leukemias in children
- 20% of adult leukemias
Treatment Issues

The goal of TKI therapy is to achieve a complete cytogenetic response within 12 months of initiation of therapy with goal of eventual major molecular response. A subset of individuals will eventually achieve a complete molecular response (undetectable BCR-ABL1 transcripts using a test with 4.5 log sensitivity).

Prognostic Issues

A 3-log decrease in the level of BCR-ABL1 fusion transcripts (major molecular response) within 18 months of beginning TKI therapy is an indicator of favorable outcome. Monitoring for recurrence using quantitative measures is crucial for detecting early relapse.

Genetics

Gene

BCR-ABL1

Mutations

- >130 mutations
- Four regions tested
  - Adenosine triphosphate binding-loop (P-loop)
  - Drug-binding sites
  - Catalytic domain
  - Activation loop

Test Interpretation

BCR-ABL1, Major (p210), Quantitative

Analytical Sensitivity

1:125,000 normal cells (chart)
