

# PTEN-Related Disorders

## Indications for Ordering

- Confirm clinical diagnosis of *PTEN* hamartoma tumor syndrome (PHTS)
- Determine if at-risk family members have a *PTEN* variant when a familial variant is unknown and affected relatives are unavailable for testing

## Test Description

- Polymerase chain reaction and bidirectional sequencing of *PTEN* coding regions, intron/exon boundaries, and promoter (600 bp region 745 bp upstream of translation start codon)
- Multiplex ligation-dependent probe amplification of *PTEN* coding regions

## Tests to Consider

### Primary Tests

[PTEN-Related Disorders \(PTEN\) Sequencing and Deletion/Duplication 2002470](#)

- Preferred initial diagnostic and predictive test for *PTEN*-related disorders

[PTEN-Related Disorders \(PTEN\) Sequencing 2002722](#)

- Acceptable initial diagnostic and predictive test for *PTEN*-related disorders

### Related Tests

[Familial Mutation, Targeted Sequencing 2001961](#)

- Useful when a pathogenic familial variant identifiable by sequencing is known

[Deletion/Duplication Analysis by MLPA 3003144](#)

- Use to assess for large deletion/duplication previously identified in a family member

## Disease Overview

### Prevalence

- Cowden syndrome (CS): at least 1/200,000
- Proteus syndrome (PS): rare
  - ~120 reported cases
- Other *PTEN*-associated conditions: unknown

### Symptoms

- Germline variants in *PTEN* gene cause several syndromes collectively referred to as PHTS
  - Associated disorders include:
    - CS
    - Bannayan-Riley-Ruvalcaba syndrome (BRRS)
    - PS
    - Proteus-like syndrome (PLS)

For disease descriptions, see table below

- Established practice guidelines for tumor surveillance should be followed for individuals with an identified germline *PTEN* variant or suspected clinical diagnosis of a *PTEN*-related syndrome

### Genetics

**Gene:** *PTEN*

**Inheritance:** autosomal dominant

### Penetrance

CS: 99% by age 30

**De novo variants:** all cases of PS and 50-90% of CS

### Variants

- Some variants may be associated with multiple phenotypes
- Type of variant detected may differ by phenotype
- Promoter variants
  - ~10% of individuals with CS do not have a *PTEN* sequence variant (Zhou, 2003)
  - Have not been identified in patients with BRRS
- Large deletions
  - 10% of individuals with BRRS do not have a *PTEN* sequence variant (Zhou, 2003)
  - Rare in CS
- Exon location
  - 65% of variants causing CS occur in exons 1-5 or the promoter
  - 60% of variants causing BRRS occur within exons 6-9

## Test Interpretation

### Sensitivity/Specificity

- Clinical sensitivity
  - 25-85% for CS in individuals meeting strict diagnostic criteria (Marsh, 1998; Tan 2011)
  - 65% for BRRS (Marsh, 1998; Zhou, 2003)
  - 20% for PS (Zhou, 2001)
  - 50% for PSL (Zhou, 2001)
  - Up to 20% for autism spectrum disorder with significant macrocephaly (Butler, 2005)
- Analytical sensitivity/specificity
  - Sequencing: 99%
  - MLPA: 90% and 98% respectively

### Results

- Positive: pathogenic variant in *PTEN* was identified
  - Confirms diagnosis of PHTS
- Negative: no variant detected
  - Decreases, but does not exclude, the probability of a *PTEN*-related disorder
- Sequence variants of unknown clinical significance may be detected

### Limitations

- Deep intronic variants and some regulatory region variants are not detected.
- Large deletions/duplications of exon 3 may not be detected.
- Breakpoints for large deletions/duplications will not be determined.
- Diagnostic errors can occur due to rare sequence variations.
